SUMMARY

Objective: To evaluate safety and refractive efficiency after posterior chamber diffractive implantable phakic contact lens (IPCL) surgery.

Material and Methods: A prospective non-randomized case-series study was performed on 54 myopic eyes of 27 patients who had undergone diffractive IPCL surgery. Corneal endothelial cell density (ECD), central corneal thickness (CCT), intra-ocular pressure (IOP), vault, uncorrected distance (UDVA), spherical equivalent (SE) and defocus curve, were all evaluated twelve months after surgery. The presence of cataracts was evaluated by slit-lamp during a postoperative follow-up.

Results: Mean age was 47 ± 2.62 years-old. Mean SE decreased, from -5.95 ± 2.56 D in a pre-operative stage, to -0.25 ± 0.25 D twelve months after surgery. Achieved UDVA was 20/20 in 24.1% of all cases, 20/25 in 74.1% of them, and 20/32 in all remaining cases. No eyes suffered lost lines of vision. The binocular defocus curve was 0.06 ± 0.05 logMAR for a -3.0 D of defocus; 0.11 ± 0.04 logMAR for a -1.5 D of defocus, and 0.08 ± 0.03 logMAR for a 0 D of defocus. Twelve months after surgery, mean ECD had decreased by 1.43 %, whereas mean CCT had increased by 0.06 %, without any significant statistical difference ($p = 0.28$ and $p = 0.93$ respectively). No difference ($p: 0.86$) in the vault was observed at 6 months vs. 12 months, as well as between IOP measurements ($p = 0.22$). There were no non-intra or postoperative complications, and, specifically, no cataracts developed either.

Conclusions: Diffractive IPCL was implanted safely. Corneal endothelial CD, CCT, vault, and IOP remained stable twelve months after surgery. Visual acuity for distance, intermediate and near sight were achieved without spectacles.

Key words: Presbyopia, phakic intra-ocular lens, refractive surgery, posterior chamber

Čes. a slov. Oftal., 76, 2020, No.5, p. 211–219

INTRODUCTION

Presbyopia is an increasing problem in adults aged over forty years. As a result, correction of presbyopia has become a developing and fast growing part of refractive surgery. Corneal procedures have their limitations in connection with the structure of the cornea and the overall size of ametropia [1-3]. It is possible to use multifocal intraocular lenses (IOL) [4]. However, extraction of a clear lens in myopic eyes is controversial due to the increased risk of retinal complications [5-7].

A phakic intraocular lens (pIOL) can correct high myopia and hyperopia with the advantage of reversibility, stability of correction and preservation of accommodation [8-

14]. It is also expected that higher quality of vision in high ametropias can be attained with the aid of pIOL in comparison with keratorefractive surgery [15-18]. Implantation of a pIOL into the anterior chamber is linked with complications, which have been described in a series of studies [19-21]. A phakic intraocular contact lens which can be implanted into the posterior chamber, termed an IPCL (Care Group, India), has demonstrated its safety and efficacy in correcting myopia and myopic astigmatism [22-24]. A new model of the lens, the "diffractive IPCL V 2.0", represents an option for correcting presbyopia. The aim of this article is to assess the safety and refractive effectiveness of the diffractive IPCL V 2.0 in patients with myopia or myopic astigmatism and presbyopia.

METHODS

Conception of study

The safety and efficacy of implantation of a diffractive IPCL was assessed in a prospective non-randomised trial. The operations were performed from February 2018 to August 2018, with subsequent two-month observation. The study was in accordance with the principles of the "Helsinki declaration" and with the consent of the ethical commission of the "Clínica de Ojos Dr. Nano". Written consent was obtained from all patients after provision of complete information about the characteristics and risks of the surgical procedure.

Criteria for inclusion and exclusion of patients

Inclusion criteria. Patients aged between 40 and 55 years with myopia, with or without astigmatism, and with stable refraction for a minimum period of one year were included in the study.

Exclusion criteria. All patients with cataract, patients in whom endothelial cell density (ECD) of the cornea was less than 2 000 cells/mm², or who had an anterior chamber depth (ACD) of less than 2.8 mm were excluded from the study; also excluded were patients with a history of glaucoma, with glaucoma, or who had undergone retinal surgery. In addition, patients with a corneal pathology (dystrophy, degeneration or trauma, which could influence corneal transparency) were excluded. In the current series, patients with hypermetropia were also excluded.

Preoperative examination and assessment parameters

All the patients underwent a complete ophthalmological baseline examination. The patients' age and sex was recorded. Preoperative assessment of the cornea (for the purpose of detecting regular or irregular astigmatism) and measurement of ACD was performed with the aid of a Pentacam instrument (Oculus, Wetzlar, Germany). Pentacam was also used to measure pupil diameter under scotopic conditions. This information was used for

the selection of the optic zone of the IPCL. The size of the IPCL was determined on the basis of horizontal white-to-white distance (IOL-Master 500®; Carl Zeiss, Germany).

In all cases the goal was emmetropia. Before the surgical procedure and also twelve months afterwards, manifest spherical equivalent (SE) and astigmatism were assessed. Postoperative uncorrected distance visual acuity (UDVA) was compared with preoperative corrected distance visual acuity (CDVA) (Snellen charts). Twelve months after the surgical procedure, the logarithm of the minimal angle of resolution (logMAR) was calculated in order to obtain the defocus curve (addition from -4.0 to +2.0 D).

Selection of addition

The size of optimal addition was calculated with the aid of our own nomogram on the basis of patient age and the degree of myopia (Table 1). A preoperative subjective evaluation of visual acuity with correction was conducted on all eyes. Two variants were available.

Variant A: A lens with the highest tolerated addition was implanted in the dominant eye. This addition was increased by 0.50 to 1.0 D, as stated in table 1, and used in the non-dominant eye as "mixed addition", which in the following years, upon increasing presbyopia, enables the patient to avoid the necessity of wearing glasses for near vision.

Variant B: If the difference between the dominant and non-dominant eye was not tolerated before surgery, identical addition was used for both eyes.

The highest level of addition, which could be subjectively tolerated, was selected according to age and degree of myopia.

ECD of the cornea and CCT were determined preoperatively and twelve months after the surgical procedure by specular endothelial microscope (TOMEY EM4000). Intraocular pressure (IOP) was measured before the procedure, 1 and 7 days afterwards, and subsequently one and twelve months after the procedure by Goldmann tonometer. Iridotomy was not performed before implan-

Table 1. Nomogram for selection of best presbyopic addition (ADD) for each eye according to age, degree of myopia, condition of dominant and non-dominant eye and patient tolerance (variant A and variant B). Dioptre (D)

Myopia	Age (in years)	Variant A		Variant B
		Dominant eye ADD (D)	Non-dominant eye ADD (D)	Both eyes with same ADD (D)
-3 to -6	40-44	1.5	2	1.5 to 2
	45-50	2	3	2.0 to 2.5
	> 50	2.5	3.5	2.5 to 3.5

tation of the IPCL. Vault of the IPCL was assessed at 6 and 12 months after surgery by an ultra-bio microscope AvistoTM; Quantel Medical.

If astigmatism was > 1.0 D, a toric diffractive IPCL V2.0 was used. Complications were evaluated during the course of the operation and afterwards, especially for the purpose of detecting signs of onset of cataract (with the aid of a slit lamp, always by the same observer), in accordance with the classification system Lens Opacities Classification System (LOCS) classification III.

Properties of diffractive IPCL V2.0 (official brochure on website <http://caregroupiol.com/products/phakic-lenses/ipcl/>)

The IPCL is a single-piece, foldable, hydrophilic acrylate injectable pIOL for the posterior chamber, which is available in Europe. It is inserted behind the iris, in which its haptic part should rest in the ciliary body. It is implanted by means of a 2.8 mm corneal incision. The construction of the lens incorporates 6 haptics for increasing stability. It has two openings in the peripheral part of the upper zone for reducing dazzling and halo effects, and four openings outside the optic zone. Version V2.0 has a central conical opening (380 μ m) in order to facilitate circulation of the chamber fluid. The thickness of the IPCL is 80 μ m. It is designed in such a manner as to correct myopia within the range of -1.00 to -33.00 dioptres (D) and hyperopia from +1.0 to +15.0 D. It has an aspherical optic zone with zero aberration. The diameter of the optic part is within the range of 5.75 to 6.20 mm, and the total size is from 11.0 mm to 14.00 mm (in gradations of 0.25 mm). The diameter of the optic part is available in variants of 6.50, 6.80, 7.20 or 7.50 mm, according to the patient's pupil size. This lens has diffractive refractive technology (trifocal optic design), with concentric rings to support addition for near vision (ADD) from +1.5 to +4.0 (with gradations of 0.5 D) and intermediary addition of +2.1 D. The diffractive zone has an angle inclination, thanks to which light dispersion is reduced to 8 % or less. The progression of the angle inclination is within the range from 6° in the centre to 65° on the periphery of the lens. The angles of this inclination decrease from the centre to the periphery; beginning at 1.8 μ m in the centre and reaching 90 μ m on the periphery.

In the current study, the selection of the optic zone and the diameter for each eye was performed with the use of an online IPCL calculator (<http://www.ipcliol.com/>). All the used lenses were of a standard size (adjustment of size was not requested).

Description of surgical technique: steps and tips.

All the operations were performed by the same surgeon. Viscoelastic materials were not used whatsoever, as published previously [24]. An incision (at an angle of 45 degrees) was made under local anaesthesia of the cornea, using a 20G V-knife. The anterior chamber was sustained by an infusion with the aid of a bimanual 23G irrigation/aspira-

tion (I/A) cannula. After the first incision, a second 2.8 mm incision was made (at an angle of 130 degrees). There followed implantation of the phakic lens, the anterior chamber was sustained by balanced saline solution (BSS). The lens was carefully unfolded by I/A cannula and the haptics were placed behind the pupil at a position of 3 and 9 o'clock. Perioperative local treatment was identical in all cases; beginning three days before the operation with the application of 0.5 % gatifloxacin and 0.09 % bromfenac four times per day, after surgery the patients continued in this treatment, with the addition of one drop of 0.05 % difluprednate four times per day for a period of four weeks.

STATISTICAL PROCESSING

The descriptive statistical results are presented as the median value, standard deviation (SD) and range. Normality of the data was checked with the aid of a Kolmogorov-Smirnov test. A Wilcoxon test was conducted to compare the differences between central corneal endothelial cell density, CCT (baseline value vs. 12 months after surgery) and vault (6 vs. 12 months after surgery). An ANOVA analysis (single-factor) was used for evaluation of IOP. P values of lower than 0.05 were considered statistically significant. The reliability coefficient (R2) for assessment of the correlation between the intended and actually attained change of spherical equivalent (SE) was calculated as a component of the linear regression analysis. A statistical analysis was conducted with the aid of the software XLMiner Analysis ToolPak (Frontline Systems Inc.). The data is available from the organisation "Clínica de Ojos Dr. Nano".

RESULTS

A total of 27 patients were operated on (54 eyes, of which a toric IPCL V.20 was used on 13 eyes). The mean age of the patients was 47 ± 2.62 years (43-53). The ratio of women to men was 15/12. All the surgical procedures were performed without any complications during the course of the operation. Cataract did not originate in any of the eyes within twelve months after surgery.

Safety of cornea, IOP and vault

Twelve months after the surgical procedure, average ECD was reduced by 1.43 % (38.74 cells/mm²) and mean CCT increased by 0.06 % (0.35 μ m), without significant statistical differences (all the values are presented in table 2). The IOP values remained similar at all follow-up examinations, without a statistically significant difference (Table 2). One day after the surgical procedure a slight increase was observed, but the IOP values always fluctuated within a normal range. In the period of 6 to 12 months after surgery, average vault decreased by 0.55 % (2.89 μ m), without statistically significant differences ($p = 0.86$), as can be seen in table 2.

Objective refraction, visual acuity and defocus curve

None of the eyes lost a single row of visual acuity, in 59.6

Table 2. Median values, standard deviation [range] from endothelial cell density (ECD), central corneal thickness (CCT), arching and intraocular pressure (IOP) were compared in different time points. A statistically significant difference was observed ($p < 0.05$).

	Baseline			After 12 months		p
Endothelial cell density (cells/mm2)	2695.11 ±184.85 [2299–3096]			2656.37 ±183.11 [2264–3002]		0.28
Central corneal thickness (µm)	510.77 ±23.43 [445–564]			511.12 ±23.40 [442–562]		0.93
Arching (mm)	Month 6			Month 12		p
	523.05 ±90.46 [300–702]			520.16 ±90.53 [299–698]		0.86
IOP (mm Hg)	Baseline	Day 1	Day 7	Month 1	Month 12	p
	13.8 ±1.5	14.25 ±1.2	13.83 ±1.3	13.74 ±1.2	13.76 ±1.2	0.22
	[11–17]	[11–16]	[12–16]	[11–16]	[12–16]	

% of eyes visual acuity was unchanged, 40.4 % of eyes showed an improvement (gain of 1 row of Snellen chart), as can be seen in graphs 1 and 2. Mean postoperative SE was -5.96 ± 2.10 D (-3.12 to -12.50), which twelve months after the surgical procedure was reduced to -0.25 ± 0.25 D ($+0.25$ to -0.75). Graph 3 presents the correlation coefficient (R^2 : 0.93), which states the strength of the correlation between the intended and actually attained change of SE. The spherical effectiveness of refractive precision is illustrated in Graph 4. Postoperative manifest astigmatism was -0.77 ± 0.59 /0 to -2.5). The attained value of astigmatism and the preoperative comparison are illustrated in Graph 5. Good results were attained for various additions of defocusing, as can be seen in Graph 6. Mixed addition (variant A) was used for 21 patients. In the remaining patients

addition was the same for both eyes (variant B).

DISCUSSION

The author of this study has experiences of the implantation of IPCL lenses for correction of patients with high myopia dating back to 2015. This study refers to the first results of the use of IPCL V2.0. Its safety and efficacy was assessed 12 months after the surgical procedure according to various aspects. These aspects are discussed below.

Presbyopia is an unresolved problem, and various surgical and non-surgical variants exist for its correction. Refractive procedures with a phakic or pseudophakic IOL are focused on improving the quality of vision and lives of patients in their fourth decade of life. Laser refractive

Graph 1. Uncorrected distance visual acuity (UDVA). procedures are not recommended for patients with presbyopia with a thin cornea and high myopia. The number of surgical procedures with a posterior chamber phakic IOL is increasing, and some studies emphasise their advantages in comparison with refractive interventions on the cornea with regard to excluding complications such as postoperative ectasia [2,25,26], refractive regression, high aberration index [3,17,18,27], problems with healing of surgical wound on cornea [28,29] and patho-

logy of the ocular surface (dry eye, neuropathic pain) [30,31]. Treatment of presbyopia in the myopic population is not easy. It is natural that the majority of people with myopia have good near vision also without the aid of glasses. After the age of forty they must change their habits (take off glasses, cease using contact lenses, start using multifocal glasses). Even individual with myopia who for a certain time after the surgical procedure have good results in terms of distance and near vision usually

eventually start to need glasses again due to presbyopia.

Implantation of a pIOL is a reversible refractive procedure, which preserves accommodation with minimal induction of higher order aberrations in comparison with photo-ablative procedures on the cornea [18]. The posterior chamber pIOL has undergone a significant improvement. However, to date there are no extensive studies on the model of the IPCL. In two studies [22,23], the authors assessed the previous model, the IPCL V1.0 (which required the performance of iridotomy). With a few small differences, both studies presented the best refractive results without complications in myopic correction and myopic astigmatism. A study has also been published on the IPCL V2.0 (new model with central opening), which presented safe and effective results [24]. The current study is the first to present the results of the diffractive IPCL V2.0 with emphasis on questions of safety and the visual result.

Question of safety: Intraocular pressure, cornea (endothelial cell density and central corneal thickness) and vault.

As is evident from the results of the current study, postoperative IOP remained the same over time, similarly as in the previously presented study relating to IPCL with the same platform (with central opening), which was performed by the same surgical technique, entirely without the use of viscoelastic materials [24]. This surgical method may have an "extra value" in the sense that it excludes potentially high values of IOP after surgery, which are connected with insufficient removal of viscoelastic material [21,32]. In addition, the safety of the procedure of implantation of the IPCL without viscoelastic materials for the cornea was assessed by means of measurement of corneal ECD and CCT. Both parameters were stable and without significant statistical differences twelve months after the surgical procedure. A similar result was attained in the previous study, although only within the framework of subsequent six-month observation of the model IPCL V2.0 [24]. With the previous platform of IPCL (V1.0), which was evaluated by different authors, analogous safety results were attained upon the use of a surgical technique with the use of viscoelastic materials [22,23]. For this reason, and for the purpose of confirming this aspect, it is essential to conduct a multicentric study comparing the existing technique with surgical procedures conducted with the aid of viscoelastic materials.

Central vault is the distance between the side of the IPCL and the anterior side of the patient's own lens. This is an important safety parameter, which at the same time is connected with the refractive result. If the size (diameter) of the IPCL is not selected correctly, a number of problems may appear – in the case of lower vault there is a greater risk of the development of cataract. A safe value of vault must be between 250 and 750 μm ; in the opposite case there is an increased risk of the occurrence of cataract. If vault reached values close to 1 000 μm , the lens had to be explanted [21,33,34]. Vault observed in this study was stable over time, without a statistically significant difference in the subsequent period of 6 to 12 months, which emphasises the postoperative stability and safety

of the IPCL with regard to the fact that cataract did not develop in any of the cases.

Visual acuity

Refractive effectiveness was demonstrated by a reduction of SE following the surgical procedure and the reliability coefficient, which approached 1 (R^2 : 0.93). No decrease of visual acuity was recorded in any of the eyes; the UDVA value was similar to preoperative CDVA, and the majority of cases attained a value of 20/25 or better. Only 1.9 % of all eyes recorded an UDVA value of 20/32. The good refractive result was similar to the results that were published previously [22-24], which confirms the information relating to the effectiveness of this lens in adjusting ametropias. The obtained defocus curve furthermore provides us with information on how well patients are able to see to various distances without the aid of glasses. The data confirms very good results for distance and near vision, with a slight decrease in medium distance vision twelve months after the surgical procedure. The normogram used in this study was designated for ensuring long-term independence of glasses (throughout the entire duration of the presbyopic period), thanks to the use of the highest tolerated additions for all patients. In the majority of cases the mixed variant was selected. The results of both strategies (mixed vs. identical addition for both eyes) were not compared; however, this concerns a further aspect which will be interesting to evaluate in future.

The diffractive model of the IPCL appears to be a very attractive choice for patients aged between 40 and 50 years. However, it is necessary to determine its effectiveness in a larger number of patients and over the course of a longer observation period. The main aspect for solution is near vision in operated myopic patients. It is well known that patients suffering from short-sightedness seek assistance for presbyopic symptoms later than others. Nevertheless, these individuals also remove their glasses when performing close-up work. Within the framework of the current series, the median age reached 47 ± 2.62 years (43-53 year old patients). The maximum subjective measured accommodation amplitude decreased by approximately 0.6 D per year of age [36], and some studies confirm that no relationship exists between refractive error and accommodation amplitude [36,37]. Furthermore, L.M. Abraham et al. come to the conclusion that a higher accommodation amplitude exists among patients suffering from short-sightedness in the age group of 35 to 44 years in comparison with patients with emmetropia and hyperopia. After patients have reached the age of 44 years, accommodation amplitude converges towards analogous values [37]. The total volume of residual accommodation from the existing publications and the total effect produced by the diffractive IPCL is therefore not clear. It is possible that the diffractive IPCL is in interaction with the patient's own lens, by which it supports the patient's residual accommodation [38]. Patients do not make use of the diffractive component of the lens while they still maintain accommodation, but as soon as presbyopia develops

within them, their brain will automatically select this upon reading, and they will not be necessitated to use glasses. For an assessment of how long these patients may remain independent of glasses, a longer observation period will undoubtedly be necessary.

In the past authors evaluated posterior chamber phakic lenses for addressing presbyopic problems, but with the use of monofocal lenses and monovision. M. Takahashi et al. [39] worked with a cohort of 21 patients with a mean age of 45.0 ± 3.8 years (within the range of 40 to 53 years) upon implantation of a Vision Implantable Collamer Lens (ICL). Thanks to the planned under-correction in the non-dominant eye, they attained acceptable results 6 months after surgery. A similar study with monovision and implantation of an ICL was published by K. Kamiya et al. [40], and related to 17 patients with a mean age of 46.1 ± 4.2 years (within the range of 40 to 53 years). After a 6 month observation period they attained independence of glasses without complications. Following a rigorous study of their limitations and problems, it is possible to state that monovision is a good variant for treating presbyopia [41].

The possibilities of intraocular lenses correcting presbyopia are increasing, although their scientific and objective evaluation is not easy, as discussed by J.L. Alio in an interesting editorial contribution [42]. A new insight and strength of this report is that it is the first study to analyse the use of a diffractive ICPL as a new variant for correcting this common problem. A further original aspect is the information presented in Table 1, which contains a nomogram for the selection of a corresponding "mixed" addition, in which preoperative subjective refraction and potential future addition are taken into consideration. This aspect will nevertheless require a longer observation period in order to enable an assessment of how long these patients will be able to manage without glasses for correction of presbyopia. The study also included a description of the used surgical technique, although this

was not its goal, with regard to the fact that the technique may influence the results. However, no comparison of techniques was conducted.

One of the limitations of this study is that aspects of quality of vision were not assessed, such as dazzling and contrast vision. An interesting study was published by Martínez-Plazou et al. [43], evaluating resulting dazzling in a procedure performed with the aid of another phakic contact lens for the anterior chamber (ICL, model V4c) with several similar characteristics as the IPCL, producing good results. A larger number of parameters of quality of vision were measured by Qin et al. [44] in a hypermetropic population, and here also good effectiveness was proven. However, the previous studies were conducted with the use of different lenses, which lacked the diffractive optics of the IPCL.

It shall therefore be necessary to assess these parameters in a future study on the diffractive IPCL V2.

CONCLUSIONS

This study confirms that twelve months after implantation of a diffractive IPCL with a surgical technique that does not use viscoelastic materials whatsoever, neither corneal ECD nor CCT were altered. After a period of 6 to 12 months after implantation of the IPCL, vault remained stable, within the framework of the safety parameters and without the onset of cataract. The obtained postoperative refraction was sufficiently good in order to attain independence of glasses, and corresponded with preoperative expectations for the spherical and toric model in the myopic population with presbyopia. To confirm the existing good results it will be necessary in future for studies to be conducted with a diffractive IPCL, with a longer observation period and by further surgeons.

Thanks

To the administrative staff of the Clínica de Ojos Dr. Nano, Institutional Audit Committee / Ethics Committee of the Clínica de Ojos Dr. Nano "and MUDr. Rodrigo M. Torres, Ph.D., for his scientific advice.

Sources of funding

I used my own means of funding as part of my scientific work reviewing the surgical results of a new intraocular lens.
