ABSTRACT

We present case of a girl deceased due to *Candida albicans* breakthrough invasive infection during the echinocandin treatment after undergoing allogeneic haematopoietic stem cell transplant for relaps of acute myeloid leukaemia. *Candida albicans* generally susceptible to all antifungal drugs wasn't considered for potential resistance and conventional blood culture positivity was too late to reveal the resistance to echinocandins. Due to severe organ toxicities (liver, kidneys) she received echinocandin as an antifungal prophylaxis, no change

was made for the treatment of *Candida albicans* infection. Later, the molecular analysis proved the mutation S645P known as being responsible for the echinocandin resistance. The post mortem analysis of fungal burden in autopsy samples showed very high levels of *Candida* DNA in gut, liver, spleen and kidneys.

KEYWORDS

invasive candida disease – haematopoietic stem cell transplant – echinocandin resistance

SOUHRN

Chrenkova V., Hubacek P., Sedlacek P., Riha P., Kodetova D., Bebrova E.: Post-mortem analýza průlomové infekce *Candida albicans* při léčbě echinokandiny u pacienta po transplantaci kmenových buněk krvetvorby

Představujeme případ úmrtí dívky na průlomovou infekci *Candida albicans* při léčbě echinokandiny po transplantaci kmenových buněk krvetvorby pro relaps akutní myeloidní leukémie. Hemokultivace prokázaly opožděně přítomnost rezistence na echinokandiny u kmene *Candida albicans*, která je obvykle považována za dobře citlivou k antimykotické terapii. Echinokandin podávaný v profylaxi nebyl z důvodu závažných orgánových komplikací (játra, ledviny)

změněn na preparát z jiné skupiny ani v léčbě invazivní infekce. Později provedené molekulární analýzy prokázaly přítomnost mutace S645P, popsané jako příčiny rezistence k echinokandinům. Dále byla provedena post-mortem analýza nálože kvasinkové infekce ve tkáních, která prokázala velmi vysoké kvantify kvasinkové DNA v zažívacím traktu, játrech, slezině a ledvinách.

KLÍČOVÁ SLOVA

invazivní kandidová onemocnění – transplantace kmenových buněk krvetvorby – rezistence na echinokandiny

Epidemiol. Mikrobiol. Imunol., 63, 2014, č. 2, s. 121–124

INTRODUCTION

Invasive *Candida* disease remains an important cause of morbidity in allogeneic hematopoietic stem cell transplant recipients [3, 9, 19]. *Candida albicans* is still the most frequently isolated causative agent [10, 16, 26] and echinocandins are the first-line agents for the treatment of *Candida albicans* sepsis according to European council for infection in leukaemia (ECIL3) guidelines [18] and European Society of Clinical Microbiology and Infectious Diseases (ESCMID) 2012

paediatric guidelines [12]. The resistance to echinocandins is rare [6], caused by mutations in the glucan synthase complex catalytic subunit (GSC1) [7, 22] and clinical failure of echinocandin treatment in case of the detected reduced susceptibility or resistance was observed [1, 11, 14, 17, 21, 23, 25]. Our report presents a case of proven breakthrough invasive *Candida* disease rapid onset during echinocandin therapy with subsequent proof of resistance mechanism and post-mortem fungal burden determination.

SOUHRNNÁ SDĚLENÍ • PŮVODNÍ PRÁCE • KAZUISTIKY

PATIENT

We present a case of 17 years old girl diagnosed with the acute myeloid leukaemia (AML) with FLT3/ITD fusion gene positive detected in May 2007. She had been treated according to the appropriate protocol (AML BFM 2004) and achieved the complete remission of the disease. During the treatment, she had developed a possible pulmonary mycosis [2] treated successfully with the amphotericin B lipid complex (ABLC) and posaconazole.

In June 2009, leucocytopenia and thrombocytopenia as first symptoms of the AML relaps were detected; therefore hematopoietic stem cell transplantation (HSCT) from an unrelated donor was indicated. Twelve days before HSCT (D-12), a relapse of AML with detection of leukemic cells in the peripheral blood was proven. She was front-line treated with one short course of idarubicin, fludarabine, cytarabine, granulocyte colony stimulating factor (IDA-FLAG) and shortly after bone marrow transplanted in aplasia after conditioning of Melphalan (140 mg/m²) and anti-thymocyte globulin (20 mg/kg of the body weight (bw)) by 10/10 HLA (human leukocyte antigen) identical unrelated donor. There were 10.2x10⁸ nucleated cells per kg of bw, 6.96x10⁶ CD34+ cells/kg bw and 3.38x10⁷ CD3+ cells/kg bw in the peripheral blood stem cell (PBSC) graft.

The standard antifungal prophylaxis started on D-49 with itraconazole 5 mg/kg/day p.o. in two daily doses (div q12h). Due to the nausea and vomiting as known adverse effects of itraconazole, the treatment was switched to voriconazole 12 mg/kg/day p.o. div q12h on D-40. Due to suspected toxic hepatopathy and colonization by *Saccharomyces cerevisiae*, echinocandin application was started on D-6 with micafungin 100 mg i.v. once daily (q24h). First week after HSCT patient got neutropenic enterocolitis with GIT bleeding, melena and severe anaemia. She developed fluidothorax in both pleural cavities shortly after. During second week after HSCT patient remained sub febrile with CRP about 100 mg/l and fluidothorax increased more on the right side and was drained without any microbiological culture finding.

On D+15, *Candida albicans* was detected in the non-invasive body-samples: oral cavity swab, nasogastric aspiration, stool, genital swab and urine and at that time no susceptibility testing was done. On D+17 the patient presented toxic hepatopathy and renal insufficiency and yeasts were detected in the blood culture. The antifungal treatment was continued by echinocandins (caspofungin 50 mg i.v. q24h). Central venous catheter (CVC), chest drains and nasogastric tube were extracted and short term CVC and two peripheral catheters were applied. Furthermore we found a positivity of mannan antigen (Platelia® *Candida* Ag, Bio-Rad, Prague, Czech Republic) in the blood sample on D+16. On D+19 the resistance to caspofungin was detected by phenotypic testing. One day later, patient was transferred to the Intensive Care Unit (ICU) presenting a renal failure, toxic hepatopathy and coagulopathy and deceased on D+21 due to the multi-organ failure. The autopsy findings confirmed disseminated candidiasis with macroscopic presence of *Candida* foci massively in spleen, liver, heart and kidney. FLT3/ITD detection used for monitoring of minimal residual disease [4] in the patient confirmed high levels of this fusion gene in the patient (positive in bone marrow, liver and spleen).

METHODS AND RESULTS

We verified the identification of *Candida albicans* isolated from three consecutive blood cultures by Auxacolor2 (Bio-Rad, Prague, Czech Republic) and ID 32C (bioMérieux, Prague, Czech Republic). The susceptibility testing was carried out by E-tests (bioMérieux, Prague, Czech Republic) using RPMI-1640 agar (Trios, Olomouc, Czech Republic) and by Sensititre YeastOne

(Trek Diagnostik, BioVendor, Brno, Czech Republic) following the manufacturer's instructions. The obtained minimum inhibitory concentrations (MIC) were >32 mg/l for caspofungin, 1.0 mg/l for micafungin, 1.5 mg/l for anidulafungin, 0.125 mg/l for fluconazole, 0.006 mg/l for voriconazole, 0.023 mg/l for posaconazole and 0.5 mg/l for amphotericin B. The reference mycological laboratory confirmed both *Candida albicans* identification and the susceptibility testing.

As consequence of the depicted resistance to caspofungin we performed a sequence analysis of the beta-D-glucan synthase catalytic subunit (GSC1/FKS1), known as the target place of echinocandins antifungal activity [7]. The DNA was isolated from the culture by the use of a protocol for yeasts of Qiagen DNA Mini Kit (Qiagen, Hilden, Germany). We used previously described primers [17] for the PCR reaction. This PCR reaction consisted of 1x Long Range PCR buffer (Qiagen, Hilden, Germany), 3.5 mM MgCl₂, 100 μM of each dNTP (Sigma-Aldrich, Prague, Czech Republic), 500 nM primers and 0.5 U Qiagen HotStar Taq polymerase (Qiagen, Hilden, Germany). The samples were tested in duplicates and the total volume of PCR reaction was 25 μl, containing 5 μl of extracted DNA. The temperatures of the thermal protocol started at 93 °C for the first 15 min, followed by 35 cycles of 93 °C for 15 s, 57 °C for 30 s and 68 °C for 2.5 min. By this reaction we obtained 2.548 bp long amplicon. On this amplicon we applied the sequence analysis using the ABI Genetic Analyzer 3130 (Applied Biosystems, Prague, Czech Republic). The comparison of the obtained sequence to wild-type strain *Candida albicans* ATCC 90028 proved the presence of previously described mutation S645P [21]. Niimi in his article describes [20] heterogeneity of yeast mutations based on the susceptibility testing results. Following his logic, in our case, the complete resistance to caspofungin and the reduced susceptibility to micafungin and anidulafungin with MIC < 2 mg/l, lead us to the conclusion that our strain of *Candida albicans* shows a heterozygosity of mutation in GSC1/FKS1 hot spot 1.

Besides this complex analysis we performed also retrospective PCR testing on *Candida* DNA quantity of the stored samples used for standard viral surveillance during post-transplant period and samples from the autopsy. DNA was extracted from the whole blood and the tissues by Qiagen DNA Blood Mini Kit and Qiagen DNA Mini Kit (Qiagen, Hilden, Germany) following the manufacturer's instructions. We used the previously described real-time PCR (RQ-PCR) approach [15]. PCR reaction consisted of 1x Qiagen PCR buffer, 4.0 mM MgCl₂, 5% of glycerol, 100 μM of each dNTP (Sigma-Aldrich, Prague, Czech Republic), 1.6 μM ROX-6 passive reference dye, 500 nM primers, 200 nM probe and 0.5 U Qiagen HotStar Taq polymerase (Qiagen, Hilden, Germany). Samples were tested in duplicates and PCR reaction was performed on ABI 7500 machine in the total volume of 15 μl, containing 2 μl of extracted DNA. The temperatures of the thermal protocol started at 95 °C for first 15 min, followed by 50 cycles of 94 °C for 15 s and 60 °C for 1 min. The standard curve was constructed on the basis of the serial decadic dilution of suspension of known CFU concentration. For a better comparison of the yeast DNA quantity in different tissues, the *Candida* quantity was normalized to 100.000 human genome equivalents (g.e.) obtained by the quantification of the albumin gene in the sample [24]. RQ-PCR on *Candida* detected a massive affection of the yeast infection in the spleen, liver, renal cortex and mucosa of proximal gastrointestinal tract (5.6x10⁷; 3.7x10⁵; 2.6 – 5.4x10⁵ and 0.2 – 2.1x10⁷ CFU normalized to 100.000 g.e. respectively) compared to the rest of the tissues such as brain and heart (6x10³ and 2x10⁴ CFU normalized to 100.000 g.e.). We found no *Candida* DNA in the blood one week before the decease.

DISCUSSION

Our case shows the possible complications with management of invasive Candida infection. Our experience shows that in rare cases, using of broad-spectrum antifungal drugs in the prophylaxis can fail with all clinical consequences. Phenotypic testing of the colonizing strains including the antifungal susceptibility profile can be fundamental in such cases, even if this testing is rather costly. Therefore, we changed our strategy of microbiological screening in haematology and oncology patients. Regular susceptibility testing of Candida albicans colonization strains in the high-risk, severely immunocompromised patients is included in our guidelines.

However, choose of antifungals in our patient was limited by concomitant diseases. Since renal insufficiency, subsequent renal failure and hepatopathy with veno-occlusive disease of the liver cannot be excluded, treatment with voriconazole or amphotericin B wasn't possible and the echinocandins were continued. Hepatopathy could also reflect dissemination of Candida.

The post-mortem analysis detected high level of minimal residual disease (MRD), this indicates non controlled leukaemia. At the same time the patient was transplanted in aplasia but wasn't in remission of the AML as known risk factor of infectious complications – especially of invasive Candida disease – during post-transplant period [13].

Our strain presents heterozygous form of resistance mutation leading to the complete resistance to caspofungin and the reduced echinocandin susceptibility in case of micafungin and anidulafungin. That time, official break-point of 2 mg/l

for echinocandins [5] could lead to omitting the resistance in case that only micafungin or anidulafungin is tested, so we are in agreement with published data leading to the break-point change [6, 8].

The Candida DNA detected quantity corresponds to the most frequently touched locations – gut mucosa, hepatosplenic affection and haematogenous dissemination in the human body. The detected quantities will serve us as reference for PCR detection in samples of patients with suspected invasive Candida disease. Our analysis of the DNA quantity in the blood before and during post-transplant period shows that no Candida DNA was found in the blood one week before the decease. This fact could be explained by possibly inadequate way of DNA extraction for Candida detection but no other method was available at that time and there is no serum left for further analysis. In this case no supplement chemical or

SOUHRNNÁ SDĚLENÍ • PŮVODNÍ PRÁCE • KAZUISTIKY

mechanical cytolysis was done in these extractions as would be recommended for *Candida* DNA detection [28] because we performed routine DNA extraction protocol for blood used for viral DNA surveillance in patient.

The described method of detection of the mutations in GSC1/FKS1 with molecular microbiology-based methods and also new developed method [27] might help us in the future with a rapid diagnosis in such cases. Together with further detailed phenotypic testing it can be the main evidence for changes in the antifungal treatment or prophylaxis.
