ABSTRACT

Aim: The aim of the study was to describe the prevalence of HIV-1 subtypes and HIV-1 strains resistant to antiretroviral therapy (ART) in HIV-positive persons newly diagnosed in Slovakia in 2019–2021.

Materials and Methods: The study group consisted of 184 HIV-positive naïve patients newly diagnosed in Slovakia from 2019 to 2021. The viral HIV-1 RNA was isolated from plasma by the QIAamp Viral RNA Mini Kit (QIAGEN, Germany). For RT-PCR and sequencing of the HIV pol region, in-house procedures were used according to the ANRS AC11 protocol for RT (reverse transcriptase), PRO (protease), and IN (integrase) [ANRS AC11 Resistance Study Group, 2015]. Analysis of sequences was performed using Sequencing Analysis Software v5.3 (Applied Biosystems®). HIV sequences were manually edited using BioEdit (version 7.2.5), compared with consensus HIV-1 sequences in the Los Alamos Sequence Database (URL 2), aligned using CLUSTAL W [Labarga et al., 2007] and BioEdit software packages (version 7.2.5) [Hall, 1999]. HIVDB Algorithm (version 9.0) of the Stanford HIV Drug resistance database (URL 1.) was used for sequence evaluation. For HIV-1 subtype analysis, the REGA HIV-1 Subtyping Tool [De Oliveira et al., 2005] and phylogenetic analysis MEGA X [Kumar et al., 2018] were used.

Results: Phylogenetic analyses performed in samples of 184 persons revealed the most prevalent subtype B (129/184, 70.11%), detected to the greatest extent in the population of men who have sex with men (MSM) (96/129 74.42%). Concerning non-B subtypes (55/184, 29.89%), subtype A was found with the highest prevalence (48/184, 26.09%) compared to subtype F (F1) (3; 1.63%), C (1; 0.54%) and circulating recombinant forms CRF02_AG (2; 1.09%), CRF01_AE (1; 0.54%). In 9.24% (17/184) of samples, 25 mutations clinically relevant and associated with HIV resistance ART were detected, of which 7.07% (13/184) to reverse transcriptase inhibitors, 1.66% (3/181) to protease inhibitors and 1.32% (2/151) to integrase inhibitors. In addition, multiclass resistance was present in 1.63% (3/184) of patients. Mutations associated with HIV resistance to ART were found in 9.30% of persons infected with subtype B.

Conclusion: Our study confirmed ongoing highest prevalence of subtype B with a slightly decreasing trend compared to last years. Detection of mutations causing HIV resistance to ART underlines the need for resistance testing in naïve patients even before the initiation of ART in Slovakia.

SÚHRN

Kovářová A., Valkovičová Staneková D., Hábeková M., Takáčová M.: Distribúcia HIV-1 subtypov a rezistencie na ART u HIV-infikovaných osôb na Slovensku (2019–2021)

Cieľ: Cieľom štúdie bolo popísať výskyt HIV-1 subtypov a HIV-1 kmeňov rezistentných na antiretrovírusovú liečbu (ART) u HIV pozitívnych osôb novo diagnostikovaných na Slovensku v rokoch 2019–2021.

Materiál a metódy: Štúdiijnú skupinu tvorilo 184 HIV pozitívnych naivných pacientov novo diagnostikovaných na Slovensku v rokoch 2019–2021. Vírusová HIV-1 RNA bola izolovaná z plazmy pomocou QIAamp Viral RNA Mini Kit (QIAGEN, Nemecko). Pre RT-PCR a sekvenovanie oblasti HIV pol sme použili interné postupy podľa protokolu ANRS AC11 pre RT (reverzná transkriptáza), PRO (proteáza) a IN (integráza) (ANRS AC11 Resistance Study Group, 2015). Analýzu sekvencií sme uskutočnili pomocou softvéru Sequencing Analysis Software v5.3 (Applied Biosystems®). HIV sekvencie boli manuálne upravené pomocou BioEdit (verzia 7.2.5), porovnané s konsenzuálnymi HIV-1 sekvenciami v Los Alamos Sequence Database (URL 2), zarovnané pomocou CLUSTAL W (Labarga et al., 2007) a softvérových balíkov BioEdit (verzia 7.2.5) (Hall, 1999). Na vyhodnotenie sekvencie sme použili algoritmus HIVDB (verzia 9.0) Stanfordskej databázy HIV liekovej rezistencie (URL 1.). Na analýzu HIV-1 subtypov sme použili nástroj REGA HIV-1 Subtyping Tool (De Oliveira et al., 2005) a fylogenetickú analýzu sme vypracovali pomocou programu MEGA X (Kumar et al., 2018).

Výsledky: Fylogenetickú analýzu sme vykonali zo vzoriek 184 osôb, kde sme odhalili najrozšírenejší subtyp B (129/184, 70,11 %) prevládajúci v populácii u mužov, ktorí majú sex s mužmi (MSM) (96/129 74,42 %). Čo sa týka non-B subtypov (55/184, 29,89 %), najrozšírenejší bol subtyp A (48/184, 26,09 %) v porovnaní so subtypom F (F1) (3; 1,63 %), C (1; 0,54 %) a cirkulujúcimi rekombinantnými formami CRF02_AG (2; 1,09 %), CRF01_AE (1; 0,54 %). U 9,24 % (17/184) vzoriek sme zistili prítomnosť 25 mutácií asociovaných s HIV rezistenciou na ART, z toho 7,07 % (13/184) na inhibítory reverznej transkriptázy, 1,66 % (3/181) na inhibítory proteázy a 1,32 % (2/151) na inhibítory integrázy. Okrem toho u 1,63 % (3/184) pacientov bola prítomná viactriedna rezistencia. Mutácie asociované s rezistenciou HIV na ART sa našli u 9,30 % osôb infikovaných podtypom B.

Záver: Naša štúdia potvrdila pretrvávajúci najvyšší výskyt subtypu B s mierne klesajúcou tendenciou v porovnaní s minulými rokmi. Detekcia mutácií vytvárajúcich rezistenciu HIV na ART podčiarkuje potrebu testovania rezistencie u naivných pacientov ešte pred začatím ART na Slovensku.

KLÚČOVÉ SLOVÁ

HIV – subtyp B – MSM – non-B subtypy – rezistencia

Epidemiol Mikrobiol Imunol, 2023;72(4):203–212

INTRODUCTION

Human immunodeficiency virus (HIV) continues to be a major global public health issue, having claimed 40.1 million lives so far [WHO, 2022]. 84.2 million people have become infected with HIV since the start of the epidemic [UNAIDS, 2022]. An estimated 38.4 million people were living with HIV at the end of 2021, two-thirds of whom (25.6 million) are in the WHO African Region [WHO, 2022]. In 2021, 1.5 million people became newly infected with HIV, and 650 000 people died from AIDS-related illnesses [UNAIDS, 2022]. There is no cure for HIV infection. However, with increasing access to effective HIV prevention, diagnosis, treatment, and care, including for opportunistic infections, HIV infection has become a manageable chronic health condition, enabling people living with HIV to lead long and healthy lives [WHO, 2022].

HIV type 1 (HIV-1) shows high genetic diversity between and within human hosts [Cuevas et al., 2015; Abram et al., 2010]. While within-host viral diversity is initially limited by the transmission bottleneck, HIV genomes quickly diversify as a result of a high viral replication rate and high error rates during replication [Lee et al., 2008]. Such high genetic diversity allows the virus to avoid the host's immune response and can lead to the development of drug resistance during treatment [Cuevas et al., 2015]. HIV-1 consists of four major phylogenetic groups: M (major), N (new), O (outlier), and P, representing independent cross-species transition from SIV in chimpanzees and gorillas to HIV in humans [Sharp and Hahn, 2011]. HIV-1 group M is responsible for the current pandemic and comprises genetically distinct subtypes (A, B, C, D, F, G, H, J, K, and, more recently, L), 101 circulating recombinant forms (CRFs) to date, and numerous unique recombinant forms (URFs) [Hemelaar et al., 2019; Yamaguchi et al., 2019]. HIV-1 subtypes are unequally distributed globally, which has been explained by different founder effects followed by local spread driven by socioeconomic and behavioral factors and circulation within and between specific risk groups [Hemelaar, 2012; Murillo et al., 2013; Junqueira and de Matos Almeida, 2016]. Subtype C is the most abundant strain worldwide and is prevalent in South and Eastern Africa and Southeast Asia [Hemelaar et al., 2019]. Subtype B is predominant in North Ameri-

ca, Western Europe, and Australia, while subtype A predominates in Eastern Europe and Central Asia, including Russia [Hemelaar et al., 2019; Magiorkinis et al., 2016]. CRFs and URFs are widely distributed in central Africa and in countries where different subtypes co-circulate [Hemelaar et al., 2019; Alaeus, 2000; Konstantinos et al., 2015]. The wide variety of subtypes, which are distributed mainly in different populations, may be used for molecular epidemiological analysis to track, and understand the dynamics and patterns of HIV-1 transmission and for developing strategic prevention programs [Paraskevis et al., 2016].

Subtype B was determined as the most prevalent genetic form in Slovakia [Hábeková et al., 2010; Chabádová et al., 2014; Čereš et al., 2018; Hábeková et al., 2023]. Slovak Republic belongs for a long time to EU states with the lowest annual incidence of HIV infection. In the last decade, we have observed an upward trend in the occurrence of new cases and the number of people living with HIV infection is also increasing. The majority of HIV infections (70.00%) in the Slovak Republic were recorded in the group of men who have sex with men (MSM). Overall, 20.00 % of infections were acquired through unprotected heterosexual intercourse (HTS), 1.20% through injecting drug use, 0.05% through blood transfusion (one man who got infected abroad in 1986), and 8.75% the route of transmission is still unknown. The highest HIV cumulative incidence has been for a long time recorded in the capital of Slovakia, Bratislava. More than 90.00% of people diagnosed with HIV infection in the Slovak Republic are on antiretroviral therapy (ART). More than 90.00% of people on ART are in viral suppression, so they should not be able to transmit to other people thanks to continuous treatment [Public Health Authority of the Slovak Republic, 2022].

This study aimed to describe the prevalence of HIV-1 subtypes and HIV strains resistant to ART in HIV-positive persons newly diagnosed in 2019–2021 in Slovakia in relationship to socio-demographical factors.

MATERIALS AND METHODS

In our study, 184 HIV-positive patients (naive to ART) newly diagnosed in Slovakia between 2019 and 2021

were included. In addition, personal data of patients regarding the route of transmission and country of origin were routinely obtained for epidemiological purposes during post-test counseling.

Isolation of viral HIV-1 RNA was performed from plasma samples using The QIAamp Viral RNA Mini Kit (QIAGEN, Germany). The nested reverse transcriptase polymerase chain reaction (RT-PCR) and sequencing of HIV pol region were carried out with the use of in-house procedures according to ANRS AC11 protocol for reverse transcriptase (RT), protease (PRO) and integrase (IN) [ANRS AC11 Resistance Study Group, 2015].

Sequence analysis of RT, PRO, and IN was performed using Sequencing Analysis Software v5.3 (Applied Biosystems®). The HIV sequences were edited manually in the BioEdit program (version 7.2.5). We compared the HIV-1 pol sequences with the consensus HIV-1 sequences available in the Los Alamos Sequence Database (URL 4), aligned using CLUSTAL W software [Labarga et al., 2007] and BioEdit software packages (version 7.2.5) [Hall, 1999]. RT sequences included codons 14–248, PRO sequences 1–99 and IN sequences 1–280. To evaluate the sequences and determine the degree of resistance, the HIVDB Algorithm (version 9.0) was used, where based on the database (Stanford HIV Drug Resistance Database, URL 1.) determined the degree of resistance and the occurrence of major and minor mutations. For phylogenetic analysis of HIV-1 subtypes, edited HIV-1 pol sequences were analysed using the REGA HIV-1 Subtyping Tool program [De Oliveira et al., 2005]. The evolutionary history was in-

ferred using the Neighbor-Joining method [Saitou and Nei, 1987]. The percentage of replicate trees in which associated taxa clustered in a bootstrap test (100 replicates) are shown next to branches [Felsenstein, 1985]. Evolutionary distances were calculated using Kimura's 2-parameter method [Kimura, 1980] and are in units of the number of base substitutions per site. Variation in velocity between sites was modelled using a gamma distribution (shape parameter = 1). This analysis included 60 nucleotide sequences. Codon positions 1st + 2nd + 3rd + non-coding, all were included. All ambiguous positions were removed for each sequence pair (pairwise deletion option). There was a total of 499 positions in the final data set. Phylogenetic analyses were performed in MEGA X [Kumar et al., 2018]. In addition, the distribution of HIV-1 and CRF subtypes in the relationship to socio-demographical indicators was investigated.

RESULTS AND DISCUSSION

Study group

Gender and Demography

Out of 184 HIV-1 positive persons 169 (91.85%) were men and 15 (8.15 %) were women (Table 1). The mean age of the patients was 38 (20–75) years, for men 38 (20–72) years, and for women 43 (23–75) years. Both, the youngest (20 years old men), as well as the oldest (75 years old men) individuals in the study group, were Slovaks.

Table 1. Distribution of HIV-1 subtypes by gender, country, and route of transmission in 2019 – 2021

	Subtype B No. (%)	Non-B subtypes No. (%)	Total No. (%)
Gender			
Male	124 (96.12)	45 (81.82)	169 (91.85)
Female	5 (3.88)	10 (18.18)	15 (8.15)
Total	129	55	184
Country of Origin			
Slovakia	124 (96.12)	41 (74.55)	165 (89.67)
Other country	5 (3.88)	14 (25.45)	19 (10.33)
Total	129	55	184
Route of transmission			
MSM Male	96 (74.42)	29 (52.73)	125 (67.93)
HTS Male	19 (14.73)	11 (20.0)	30 (16.30)
HTS Female	5 (3.87)	9 (16.36)	14 (7.61)
Unknown Male	9 (6.98)	5 (9.09)	14 (7.61)
Unknown Female	0 (0.00)	1 (1.82)	1 (0.55)
Total	129	55	184

MSM – men having sex with men, HTS – heterosexual contact, No. – number of people

Out of 184 participants, there were 165 (89.67%) Slovaks and 19 foreigners (10.33%): from them 14 (7.61%) Ukrainians, 2 (1.09%) Polish, 1 (0.54%) Czech and 2 (1.09%) persons of unknown nationality. Out of 169 men, 158 (85.87%) were Slovaks and 11 (5.98%) were foreigners while out of 15 women, 7 (3.80%) were Slovaks and 8 (4.35%) were Ukrainians.

Routes of HIV transmission

Most of the patients were infected by sexual contact between men (125: 67.93%), followed by patients infected by unprotected heterosexual contact (44: 23.91%) and by unknown routes of transmission (15: 8.15%). Similar results were obtained in Slovakia in 2004–2008 and 2009–2012 when more than half of HIV-1 infected patients were MSM. Similarly, the Czech Republic, reported long-term highest incidence of newly diagnosed HIV infections among MSM (79.00%) [Mravčík et al., 2017]. Proportion of men vs. of women remains also like the years 2004–2012 among newly diagnosed HIV cases in Slovakia [Chabadová et al., 2014; Hábeková et al., 2010]. However, as the number of foreigners (Ukrainian emigrants) increased during 2019–2021, the ratio among HIV-infected women decreased [Public Health Authority of the Slovak Republic, 2022].

HIV-1 B subtype

The findings of this study, which describe the distribution of HIV-1 subtypes by gender, country, and route of transmission, as well as the epidemiological data of people infected with HIV-1 non-B viruses diagnosed between 2019 and 2021, are summarized in Tables 1 and 2.

Analysis of HIV-1 strains showed that 129 (70.11%) of all 184 patients, 124 Slovaks, and 5 foreigners were infected with HIV-1 subtype B viruses (see Table 1). Subtype HIV-1 B was discovered to be the most prevalent genetic form in Slovakia during our study as well as in previous years, but with a slight downward trend compared to previous years. The highest incidence of subtype B in Slovakia was observed in 2004–2008 (93.0%), and the lowest was in our observed period (2019–2021, 70.11%). Between those years, the occurrence of subtype B in Slovakia was as follows: in 2009–2012 (86.11%), 2015–2016 (80.30%), and in 2017–2018 (82.30%) [Hábeková et al. 2010; Chabadová et al., 2014; Čereš et al., 2018; Hábeková et al., 2023] which is also confirmed by the SPREAD program. SPREAD program analysed a set of samples in newly diagnosed HIV-positive persons in Western, Central, and Eastern Europe and sub-Saharan Africa from 2002–2010, with subtype B being the dominant subtype in these countries (6310/9588, 65.80%) [Hofstra et al., 2016]. This program continued also in the years 2011–2013, including the states of Central, Mediterranean, Northern, and Western Europe, and subtype B prevailed in this period as well [Hofstra et al., 2019]. In Central European countries such

as Poland, subtype B remains the most common variant to date, shared by 85.90% of the study population, and is still prevalent among MSM in 2015–2019 [Serwin et al., 2021]. This observation is consistent with a previous report from Poland from 2008–2014, where 86.90% of recorded infections developed from the HIV-1 B lineage [Parczewski et al., 2016]. In 2014–2019 the predominant HIV-1 subtype in Croatians was subtype B (91.30%) [Oroz et al., 2019]. On the contrary, in the study from Greece HIV-1 sequences were found with subtype B only in 50.44% and subtype A1 in up to 49.56% of persons [Kostaki et al., 2022]. In a study from Belgium in 2013–2019 less than half of the patients (47.50%) were infected with the subtype B virus [Mortier et al., 2022]. It appears, a decline in subtype B has been observed in Europe, which may be due to the economic migration and refugee crisis and the increasing circulation of non-B subtypes among the native European population [Beloukas et al., 2016; Neogi et al., 2014; Hauser et al., 2018].

In our study, regarding the data on the route of transmission being infected with a subtype B virus was much more common among MSM than patients in other transmission groups (96/129; 74.42%) – see Table 1. Similar results were observed in Slovakia in studies from 2004–2008 (66.40%) and 2009–2012 (74.20%) [Hábeková et al., 2010; Chabadová et al., 2014]. Other studies also revealed that infection with HIV-1 subtype B is most common in Poland through MSM comparable to the HIV epidemic in the Netherlands [Serwin et al., 2022; Wymant et al., 2022]. A study from Slovenia also confirmed that the HIV-1 epidemic is predominantly affecting MSM infected with subtype B [Lunar et al., 2015]. In Bulgaria 1988–2018 the higher incidence of subtype B was found in MSM (56.70%) compared to heterosexuals (38.60%) [Alexiev et al., 2020]. Mustafa et al. performed phylogenetic and phylodynamic analysis using 21 007 publicly available B sequences from Europe and Asia and found MSM to be the primary high-risk group responsible for subtype B transmission, too [Mustafa et al., 2023].

HIV-1 non-B subtypes

Phylogenetic analysis revealed 55 of 184 HIV-1 non-B subtypes (29.89 %) in 41 Slovaks and 14 foreigners (Figure 1). Subtype A (48; 26.09 %) dominated in Slovakia, while other subtypes and circulating recombinant forms (CRF) were identified as follow: F (F1) (3; 1.63%), C (1; 0.54%), CRF02_AG (2; 1.09%) and CRF01_AE (1; 0.54%) (Table 2). It is obvious that the prevalence of non-B subtypes increased almost twice in Slovakia as compared to the period of 2004–2008, 2009–2012, 2015–2016, and 2017–2018 [Hábeková et al., 2010; Chabadová et al., 2014; Čereš et al., 2018; Hábeková et al., 2023]. We originally assumed that the majority of subtypes A would be transmitted to Slovakia by foreigners originating from Eastern Europe (Ukraine), but

Table 2. Epidemiological data of patients infected with HIV-1 non-B viruses in 2019–2021

MSM – men having sex with men, HTS – heterosexual contact, No. – Number of people.

In our study, 29 (52.73%) MSM were associated with non-B infections, followed by heterosexuals (20, 36.36 %), and cases of the unknown route of transmission (6, 10.91%) – see Table 2. It appears that in Slovakia male-to-male sexual contact surpassed heterosexual contact as the most common route of HIV transmission in patients infected with the non-B subtype from 2004 to 2012 [Hábeková et al., 2010; Chabadová et al., 2014]. We assume that HIV-1 diversity is increasing in Slovakia due to immigration flows and travel, which causes the presence of new viral subtypes and new recombinant forms with consequences for public health.

Spread of resistant strains of the HIV virus

In our study, 25 mutations were associated with ART resistance in 17 of 184 (9.24%) HIV-infected individuals. In addition, mutations associated with HIV resistance to non-nucleoside/non-nucleotide inhibitors of reverse transcriptase (NNRTIs), nucleoside/nucleotide inhibitors of reverse transcriptase (NRTIs) and NRTIs/NNRTIs were found in 13 (7.07%), 2 (1.09%) and 2 (1.09%) out of 184 patients, respectively. Moreover, mutations associated with resistance to protease inhibitors (PIs) were present in 3 of 181 (1.66%) persons and to integrase inhibitors (INSTIs) in 2 of 151 (1.32%) persons (Table 3).

Table 3. Occurrence of HIV-1 resistance to ART in HIV-positive patients newly diagnosed in the Slovak Republic in 2019–2021

		NRTI	NNRTI	PI	INSTI
Patients	S/R	No. (%)	No. (%)	No. (%)	No. (%)
Slovaks	S	166 (99.40)	157 (94.01)	164 (98.20)	136 (98.55)
	R	1 (0.60)	10 (5.99)	3 (1.80)	2 (1.45)
	total	167	167	167	138
Foreigners	S	16 (94.12)	14 (82.35)	14 (100.00)	13 (100.00)
	R	1 (5.88)	3 (17.65)	0 (0.00)	0 (0.00)
	total	17	17	14	13
All	S	182 (98.91)	171 (92.93)	178 (98.34)	149 (98.68)
	R	2 (1.09)	13 (7.07)	3 (1.66)	2 (1.32)
	total	184	184	181	151

S – sensitive, R – resistant, NRTI – nucleoside/nucleotide inhibitor of reverse transcriptase, NNRTI – non-nucleoside/non-nucleotide inhibitor of reverse transcriptase, PI – protease inhibitor, INSTI – integrase inhibitor, No. – Number of patients

Multiclass resistance was observed in 3 (1.63%; 2 Slovaks and 1 foreigner) patients. Mutations associated with NRTIs were as follow: M41I, D67N, T69D, K70R, M184V, T215F, K219Q and T215S, with NNRTIs A98G, K101E, K103N, V108I, V108VI, E138A, V179VD, Y181Y-CFS, F227L, with PIs: M46I, M4V6L, I84 and with INSTIs: L74M, S230SGR, D232DN, R263K. The incidence of mutations associated with resistance to ART in HIV-infected naive patients was firstly described in Slovakia in 2015–2016 [Čereš et al., 2018]. The higher prevalence of mutations associated with NNRTIs in Western Europe was confirmed by a study by Mortier et al., 2022. They found that many resistance mutations impacted the sensitivity for NNRTIs (11.40%), followed by NRTIs (6.20%), PIs (2.40%), and INSTIs (0.56%) respectively. Multiclass resistance was observed in 2.40% (88/3708) of persons in Belgium in 2013–2019 [Mortier et al., 2022]. Pingarilho et al. found the highest level of NNRTIs resistance (9.70%) in patients captured in Portugal in 2014–2019 [Pingarilho et al., 2022]. Klundert et al. sequenced the RT and PRO genes from 812 HIV-1 positive persons (from Ukraine: 191 patients, 2019–2020; Georgia: 201 patients, 2013–2017 and Russia: 420 patients, 2019–2020) for ART initiation and confirmed the highest the prevalence of mutations against NNRTIs (106, 12.68%) [Klundert et al., 2022].

Mutations A98G and E138A associated with NNRTIs represented the largest proportion of all detected mutations in our study. A98G mutation occurred in 4 of 184 (2.17%; all Slovaks) patients. A98G is a relatively non-polymorphic accessory NNRTI-resistance mutation. It occurs in 0.10–0.50% of untreated persons depending on subtype. It has been selected primarily

in persons receiving Nevirapine (NVP) and Efavirenz (EFV). It reduces NVP, EFV, Rilpivirine (RPV) and Doravirine (DOR) susceptibility about 2-fold [Melikian et al., 2014; Vingerhoets et al., 2010; Westen et al., 2013; Asante-Appiah et al., 2021; Rhee et al., 2022]. The E138A mutation was present in 4 of 184 patients (2.17%; 3 Slovaks and 1 foreigner). E138A is a polymorphic mutation that ranges in prevalence from about 2.00–5.00% in ART-naive persons depending on subtype. It reduces Etravirine (ETR) and RPV susceptibility about 2-fold [Azijn et al., 2010; Melikian et al., 2014; Lai et al., 2014; Tambuyzer et al., 2011, Rizzardini et al., 2020]. Another mutation K101E causing resistance to NNRTIs was observed in 2 of 184 individuals (1.09%; all Slovaks). This mutation was also detected in 3.7% of patients in Croatia in 2014–2017 [Oroz et al., 2019]. K101E is a non-polymorphic mutation and usually occurs in combination with other NNRTI-resistance mutations. Alone it confers 3–10-fold reduced susceptibility to NVP and about 2-fold reduced EFV, ETR, and RPV susceptibility [Azijn et al., 2010; Rimsky et al., 2012; Melikian et al., 2014; Feng et al., 2015; Lai et al., 2014].

In our study, the T215F/S mutation was detected in 2 of 184 persons (1.09%) from them 0.60% (1/167) was Slovak. This mutation causes resistance to the drug Zidovudine (AZT) (URL 2). Matuzzi et al. reported the occurrence of the T215D/S mutation in 1.50% (10/668) of Italians [Matuzzi et al., 2020] like as in Croatia (T215S: 7.40%; T215D: 1.70 %) in 2014–2017 [Oroz et al., 2019].

M46I/L was the most commonly detected mutation among PIs (2/181; 1,10%) it was found in 1.20% of Slovaks (2/167). M46IL mutation is non-polymorphic creating resistance to Atazanavir (ATV) and Lopinavir

PŮVODNÍ PRÁCE

(LPV) (URL 3). The study by Klundert et al. also confirmed this mutation as the most common (0.86%) in patients from Eastern Europe and Russia in 2013–2020 [Klundert et al., 2022]. In Portugal, and Italy this mutation was described in 0.60% and 0.40% of patients, respectively [Pingarilho et al., 2022; Matuzzi et al., 2020].

Mutation R263K causing resistance to INSTIs was found in 2 of 151 (1.32%) of which 1.45% (2/138) patients were Slovaks. No mutations to any INSTIs were found in patients in Ukraine. Similarly, mutations against PI were not confirmed in a study of patients from Ukraine [Klundert et al., 2022]. R263K is a non-polymorphic mutation and decreases sensitivity to DTG, Bictegravir (BIC), and Cabotegravir (CAB) approximately 2-fold [Tsiang et al., 2016; Rhee et al., 2019; Rhee et al., 2022].

In HIV-1B and HIV-1A infected patients, mutations associated with HIV resistance to ART were present in

12 of 129 (9.30%) and 5 of 48 (10.42%) persons, respectively. The predominant route of transmission of all resistant strains was MSM (12/17; 70.59%) – Table 4.

CONCLUSION

The findings of our study confirmed the long-term highest incidence of subtype B in HIV-1 positive patients newly diagnosed in Slovakia in 2019 – 2021, with a slightly decreasing trend compared to last year. Sexual contact between men remained the main risk factor of HIV-1 infection associated mostly with HIV-1 B subtype infection. Despite increased migration in Europe in recent years, no new subtypes have been detected in Slovakia. Evidence of mutations causing resistance to ART in naive patients highlights the significance of continuing ART resistance testing in newly diagnosed patients before initiating adequate treatment.

Table 4. Prevalence of most frequently detected mutations in newly diagnosed antiretroviral-naive HIV-infected patients in Slovakia in 2019–2021

No. of patient	NRTI	NNRTI	PI	INSTI	Subtype	Route of transmission
	S/R	S/R	S/R	S/R		
1. Slovak	S	A98G, V179VD	S	S	B	MSM
2. Slovak	S	E138A	S	S	A(A1)	HTS
3. Slovak	S	V108I	S	S	B	HTS
4. Slovak	S	A98G, K101E	S	R263K, L74M	B	MSM
5. Slovak	M41I, D67N, T69D, K70R, M184V, T215F, K219Q	K103N	S	S	B	MSM
6. Slovak	S	A98G, K101E	S	S	B	unknown
7. Slovak	S	S	S	R263K, S230SGR, D232DN	B	MSM
8. Slovak	S	S	I84V	S	B	MSM
9. Slovak	S	E138A	S	S	B	MSM
